

Stat 102C HW3: Answer Key

Muzhou Liang

May 21, 2014

Problem 1

```
> SAW = function(n = 5){
+   map = matrix(FALSE, nrow = 2*n+1, ncol = 2*n+1)
+   r = c = n+1
+   w = 1
+   for (i in 1:n) {
+     map[r, c] = TRUE
+     opt = c('up', 'right', 'down', 'left')
+     # if up is occupied, delete "1" in options
+     if (map[r-1, c] == TRUE) opt = opt[-which(opt == 'up')]
+     if (map[r, c+1] == TRUE) opt = opt[-which(opt == 'right')]
+     if (map[r+1, c] == TRUE) opt = opt[-which(opt == 'down')]
+     if (map[r, c-1] == TRUE) opt = opt[-which(opt == 'left')]
+     nopt = length(opt)
+     if (nopt == 0) {
+       w = 0
+       break
+     }
+     w = w * nopt
+     dir = sample(opt, 1)
+     if (dir == 'up'){
+       r = r - 1
+     } else if (dir == 'right'){
+       c = c + 1
+     } else if (dir == 'down'){
+       r = r + 1
+     } else {
+       c = c - 1
+     }
+   }
+   pathlength = sum(map)
+   res = list("w" = w, "length" = pathlength)
+   return(res)
+ }
```

```
> res = replicate(1e5, SAW(10))
> mean(unlist(res[1,]))
```

```
[1] 44034.72
```

Problem 2

```
> RW3 = function(t = 1e2, p = c(1, 0, 0), k11 = 0.5, k12 = 0.25,
+           k13 = 0.25, k21 = 0.25, k22 = 0.5, k23 = 0.25,
+           k31 = 0.25, k32 = 0.25, k33 = 0.5) {
+   states = c(1, 2, 3)
+   K = matrix(c(k11, k12, k13, k21, k22, k23, k31, k32, k33), 3)
+   if(!(sum(K[, 1]) == 1 & sum(K[, 2]) == 1 & sum(K[, 3]) == 1)) {
+     print('Row sum is not 1!')
+     break
+   }
+   for (i in 1:t) {
+     p1 = sum(p * K[1, ])
+     p2 = sum(p * K[2, ])
+     p3 = sum(p * K[3, ])
+     p = c(p1, p2, p3)
+   }
+   return(p)
+ }
```

We can set different $p^{(0)}$ as $(1, 0, 0)$, $(0, 1, 0)$, $(0, 0, 1)$. The results are shown as below. We find that no matter what $p^{(0)}$ is, $p^{(t)}$ is always close to the uniform distribution.

```
> RW3(p = c(1, 0, 0))
```

```
[1] 0.3333333 0.3333333 0.3333333
```

```
> RW3(p = c(0, 1, 0))
```

```
[1] 0.3333333 0.3333333 0.3333333
```

```
> RW3(p = c(0, 0, 1))
```

```
[1] 0.3333333 0.3333333 0.3333333
```

```
> RW3Unif = function(t = 1e2, p = c(1, 0, 0), k11 = 0.5, k12 = 0.25,
+           k13 = 0.25, k21 = 0.25, k22 = 0.5, k23 = 0.25,
+           k31 = 0.25, k32 = 0.25, k33 = 0.5) {
+   z = matrix(0, nrow = t, ncol = 3)
+   for (i in 1:t) {
+     z[i, ] = RW3(i, p, k11, k12, k13, k21, k22, k23, k31, k32, k33)
```

```

+   }
+   diff = apply(z, 1, FUN = function(x){sum(abs(x - 1/3))})
+   return(diff)
+ }
> t = 20
> abdiff = RW3Unif(t)
> plot(1:t, abdiff, type = 'l', xlab = 't', ylab = '|pt - U|')
> abline(h = 0, lty = 2)

```

The result below suggests that $p^{(t)}$ will be close to another distribution if you change the transition matrix.

```

> RW3(t = 1e2, k12 = 1/6, k13 = 1/3, k31 = 1/12,
+       k32 = 1/6, k33 = 3/4)

```

```

[1] 0.2142857 0.2500000 0.5357143

```

Problem 3

```

> RWM = function(t = 1e2, M = 1e4, p0 = 1, k11 = 0.5, k12 = 0.25,
+               k13 = 0.25, k21 = 0.25, k22 = 0.5, k23 = 0.25,
+               k31 = 0.25, k32 = 0.25, k33 = 0.5) {
+   states = c(1, 2, 3)
+   K = matrix(c(k11, k12, k13, k21, k22, k23, k31, k32, k33), 3)
+   if(!(sum(K[, 1]) == 1 & sum(K[, 2]) == 1 & sum(K[, 3]) == 1)) {
+     print('Row sum is not 1!')
+     break
+   }
+   people = rep(p0, M)
+   for (i in 1:t) {

```

```

+   # get the number of people at 1
+   n1 = sum(people == 1)
+   n2 = sum(people == 2)
+   n3 = sum(people == 3)
+   # get the index of people at 1
+   index1 = which(people == 1)
+   index2 = which(people == 2)
+   index3 = which(people == 3)
+   # draw the next states for those at 1
+   move1 = sample(states, n1, replace = TRUE, prob = K[1, ])
+   move2 = sample(states, n2, replace = TRUE, prob = K[2, ])
+   move3 = sample(states, n3, replace = TRUE, prob = K[3, ])
+   people[index1] = move1
+   people[index2] = move2
+   people[index3] = move3
+ }
+ p1 = sum(people == 1)/M
+ p2 = sum(people == 2)/M
+ p3 = sum(people == 3)/M
+ p = c(p1, p2, p3)
+ return(p)
+ }

```

The estimated $p^{(t)}$ is shown as below.

```

> RWM(t = 1e2, M = 1e5)

[1] 0.33140 0.33268 0.33592

```

The estimated $p^{(t)}$ will be different if we change the transition probabilities.

```

> RWM(t = 1e2, M = 1e5, k12 = 1/6, k13 = 1/3, k31 = 1/12,
+   k32 = 1/6, k33 = 3/4)

[1] 0.35631 0.38619 0.25750

```
